

Cross-border Acquisitions and Labor Regulations

Ross Levine, Chen Lin and Beibei Shen*

March 2015

Abstract

Do labor regulations influence the reaction of stock markets and firm profitability to cross-border acquisitions? We discover that acquiring firms enjoy smaller abnormal stock returns and profits when targets are in countries with stronger labor protection regulations, i.e., in countries where laws, regulations, and policies increase the costs to firms of adjusting their workforces. These effects are especially pronounced when the target is in a labor-intensive or high labor-volatility industry. Consistent with labor regulations shaping the success of cross-border deals, we find that firms make fewer and smaller cross-border acquisitions into countries with strong labor regulations.

We received helpful comments from Yona Rubinstein, David Sraer and seminar participants at the University of California, Berkeley.

1. Introduction

Cross-border acquisitions account for a large and growing proportion of all acquisitions. The dollar value of cross-border acquisitions rose from an average of \$300 billion per annum during the 1990s to an average of almost \$800 billion per annum since 2000. Furthermore, the proportion of all acquisitions, domestic and international, accounted for by cross-border deals rose from 24% to 39%. Firms increasingly look beyond national borders in conducting mergers and acquisitions.

Researchers have focused on the financial and corporate governance determinants of cross-border acquisitions. Erel et al. (2012) show that exchange rate changes and changes in relative stock market valuations influence the incidence and direction of international deals. Rossi and Volpin (2004), Bris and Cabolis (2008), and Chari et al. (2009) demonstrate that firms in countries with stronger corporate governance systems have a higher likelihood of purchasing firms in other countries. The nationalities of owners and directors matter too. Ferreira et al. (2010) find that foreign institutional owners facilitate cross-border acquisitions, and Masulis et al. (2012) find that firms with foreign independent directors make better cross-border acquisitions when the target firms are from the directors' home economies.

But, researchers have not yet studied how the broad set of laws, regulations, and policies shaping labor markets—"labor regulations"—influence cross-border acquisitions. Researchers have dissected the impact of offshoring and multinational firms on wages and employment (e.g., Revenga, 1992; Grossman and Rossi-Hansberg, 2008; Desai et al., 2009; and Harrison and McMillan, 2011). But, they have not (to our knowledge) evaluated whether differences in the degree to which countries protect the employed and assist the unemployed influence cross-border acquisitions.

This is surprising. Besides influencing a large corporate expense—expenditures on wages and benefits, labor regulations shape the costs of hiring, firing, and adjusting the hours of workers, with potentially large effects on firm performance (Botero et al., 2004). Labor market flexibility could be especially important for the success of acquisitions since acquiring firms

often restructure targets to minimize labor costs and maximize synergies. Thus, cross-country differences in labor markets might influence cross-border acquisitions and the profitability of those deals.

In this paper, we provide the first assessment of the relationship between cross-country differences in labor regulations and cross-border mergers and acquisitions. Specifically, we address the following questions. Are cross-country differences in labor regulations associated with (1) how an acquiring firm's stock price responds to a cross-border acquisition and (2) how an acquiring firm's profits change after a cross-border deal?

To address these questions, we use a sample of cross-border transactions in the Securities Data Company database across 50 countries over the period from 1991 through 2012. This includes transactions between 2,450 ($=50 \times 49$) country-pairs. We examine individual deals. We assess the cumulative abnormal stock returns (CARs) and the abnormal return on assets (ROAs) of acquiring firms following cross-border acquisitions. To calculate CARs, we follow Bris and Cabolis (2008) and use a two-factor international market model in which one factor is the local market returns and the second factor is the world market return. To compute abnormal ROA, we follow Lin et al. (2011) and Harford et al. (2012) and adjust the firm's ROAs by median industry ROAs. Before the cross-border deal, we calculate the abnormal ROAs of the (artificially) combined firm based on the relative sizes and industrial compositions of the two firms. After the acquisition, we use the acquiring firm's abnormal ROA.

We use three measures of labor regulations. First, Botero et al. (2004) provide cross-country measures of the degree to which laws impede employers from firing workers, increasing work hours, or using part-time workers. Such interventions increase the costs to employers of adjusting their workforces. Second, the OECD provides panel measures of the strictness of regulations on dismissals, including procedural inconvenience, notice and severance pay, and difficulty of dismissal. Such dismissal protections increase the procedures and costs involved in firing workers. Third, Aleksynska and Schindler (2011) provide panel data on the proportion of the unemployed covered by unemployment benefits. More generous unemployment benefits

might increase labor costs by boosting the reservation wages of the unemployed. For brevity, we use the phrases “stronger” and “weaker” labor regulations to describe the degree to which laws and policies protect the employed and aid the unemployed.

With these data, we evaluate how an acquiring firm’s CAR and abnormal ROAs respond to a cross-border acquisition. The key explanatory variable is the difference in labor regulations between the countries of the target and acquirer. The regressions control for acquirer country, target country, year, and acquirer industry fixed effects, and in some specifications, we also include acquirer-target pair effects to control for all country-pair traits. We control for deal-specific traits, geographic distance between the acquirer and target, as well as time-varying country characteristics, such as Gross Domestic Product (GDP) per capita.

We find a strong empirical connection between labor regulations and both abnormal stock returns and profits. An acquirer’s CARs and abnormal ROAs respond more positively when the target is in a country with weaker labor regulations than those of the acquiring firm. The abnormal ROAs results are robust across the different measures of labor regulations and specifications. The results on the relationship between CARs and the labor protection law index are more fragile. As we now discuss, this fragility reflects weakness in precisely identifying those target firms within a country are likely to be most influenced by labor regulations and those which are likely to be influenced least.

We extend these analyses by recognizing that labor regulations might differentially affect firms. In particular, the success of firms in some industries might depend more on labor market flexibility than the success of firms in other industries. If this is the case, then the stock market’s reaction to a firm acquiring a target will be more sensitive to labor regulations when the target is in an industry that relies heavily on labor market flexibility. Failure to account for these differences might hinder the identification of the impact of differences in labor regulations on acquirer CARs and abnormal ROAs.

Thus, we examine the relationship between labor regulations and changes in an acquiring firm’s CAR and abnormal ROAs while differentiating by the degree to which the target is in a

“labor dependent industry,” an industry in which firm performance depends heavily on labor markets. We use U.S. data to create two benchmark measures of the degree to which a firm is in a labor dependent industry: (1) “labor intensity” equals labor and pension expenses relative to sales and (2) “labor volatility” equals the volatility of employment relative to assets. We then redo the analyses of how an acquiring firm’s stock returns and profits respond to a cross-border acquisition while further differentiating by the degree to which the target firm’s industry depends on labor markets, as measured by labor intensity and labor volatility.

We find that the CARs and abnormal ROAs of acquiring firms respond most positively to cross-border acquisitions of targets in countries with comparatively weak labor regulations when the target is in a labor dependent industry. In turn, when the target is in an industry in which labor regulations are unlikely to influence firm profitability, the stock market and profits do not respond much to cross-border differences in labor regulations. The relationship between cross-border differences in regulation and acquirer CARs and abnormal ROAs is especially large when theory suggests those differences should matter most—when the performance of the target industry depends heavily on labor market flexibility.

We also extend these analyses by assessing the relationship between differences in labor regulations and the number and value of cross-border acquisitions. If labor regulations shape the stock price reaction to cross-border acquisitions and profitability of such deals, then this should be reflected the incidence and size of cross-border acquisitions when differentiating by country-pairs. To check the consistency of our deal level analyses with firm-level decisions to engage in cross-border mergers and acquisitions, we regress the number, value, and deal size of cross-border acquisitions on the difference between labor regulations in the target and acquirer countries. Besides conditioning on acquirer country, target country, and acquirer industry fixed effects, we control for acquirer and target country characteristics, such as gross domestic product (GDP) per capita and population, as well as acquirer-target traits, such as geographic distance and whether they have the same major language and religion.

We find that a country’s firms acquire more firms and spend more on each acquisition in

a country if that target country has weaker labor regulations than the regulations in the acquirer country. That is, firms find targets in countries with weaker labor regulations more appealing than similar targets in countries with comparatively strong labor regulations. For example, when the target country has one-standard deviation lower labor protection laws than the median country, our estimates suggest that the volume of cross border acquisitions will be almost 60% higher. As another example, consider China, which has labor protections that are average in our sample. About 67% of its cross-border acquisitions flow to countries with weak labor protection laws (below the 25th percentile of the employment law distribution), while only 9% flow to countries with strong labor protection laws (above the 75 percentile of the distribution). These results are consistent with this paper's core findings: acquiring firms enjoy larger CARs and abnormal ROAs after a cross-border acquisition if the target is in a country with weaker labor regulations than the acquirer country's labor regulations.

Our work relates to research on the role of labor in corporate decisions. Considerable work shows that as labor and labor unions become more powerful, this influences corporate cash holdings (Klasa et al., 2009), capital structure (Matsa 2010), tax aggressiveness (Chyz et al., 2013), firm investments (Agrawal 2012, and Faleye, et al., 2006), and managerial performance (Atanassov and Kim, 2009). Rather than focusing on how a firm's labor unions alter its behavior, we examine the association between cross-country differences in labor regulations and cross-border acquisition activity, the stock market response to such deals, and changes in the profitability of the acquiring firm after it makes the purchase. A notable paper is John, Knyazeva, and Knyazeva (2014). Using a sample of U.S. publicly listed firms, they find that acquirers from the states with strong labor rights experience on average 0.5% lower acquisition announcement returns (i.e. 5 day CARs), which suggest the stakeholder-shareholder conflict of interest in acquisition decision making. Moreover, they find that the acquirers from the strong labor rights states are more likely to bid for targets in the strong labor rights states and with high labor costs. In contrast, using a comprehensive sample of international data, we find that acquirers from countries with strong labor regulations are more likely to acquire a target in a weak labor

regulation country. Moreover, we find that an acquirer's CARs and abnormal ROAs respond more positively when the target is in a country with weaker labor regulations than those of the acquiring firm. These international evidence complements the U.S. evidence documented by John et al., (2014).

The remainder of the paper is organized as follows. Section 2 describes the data. In section 3, we present the empirical analyses, while Section 4 concludes.

2. Data, Summary Statistics, and Preliminaries

2.1 Labor regulations

We use three measures of the degree to which labor market laws, regulations, and policies protect workers and aid the unemployed. First, *Employment law* measures the degree to which laws, regulations, and policies impede employers from firing workers, increasing work hours, or using part-time workers. *Employment law* was constructed by Botero et al. (2004) to reflect the incremental cost to employers of deviating from a hypothetical rigid contract, in which the conditions of employment are specified for all employees and no employee can be fired. More specifically, *Employment law* is larger when it is more costly for employers to (1) use alternative employment contracts, such as part-time employment, to avoid limits on terminating workers or providing mandatory benefits; (2) increase the number of hours worked, either because of limits on hours worked or because of mandatory overtime premia; and (3) to fire workers, where the costs reflect the notice period, severance pay, and any mandatory penalties, as well as the costs associated with following the procedures associated with dismissing workers. Thus, besides providing information on the degree to which laws protect employees, *Employment law* is an index of the costs to firms of adjusting their labor forces.

Our second measure of labor protection is the *employment protection law index (EPL)* measures the procedures and costs associated with dismissing workers. *EPL* was compiled by the

OECD and incorporates three aspects of dismissal protection:¹ (1) procedural inconvenience that employers face when starting to fire workers, such as notification procedures and consultation requirements; (2) length of the notice period and severance pay, which vary by tenure of the workers; (3) difficulty of dismissal, as determined by the circumstances in which it is possible to fire workers and the compensation and reinstatement possibility following unfair dismissal. This *EPL* index is measured annually, so it captures country-level changes in employment protection. This allows us to control for acquirer-target fixed effects.

Third, *Unemployment coverage* equals the ratio of the number of recipients of unemployment benefits to the number of unemployed and is from Aleksynska and Schindler (2011). *Unemployment coverage* provides information on the generosity of unemployment benefits. To the extent that such benefits increase the reservation wages of unemployed workers and reduce the rate at which unemployed workers accept job offers, *Unemployment coverage* provides information on the costs to firms of hiring workers. Since *Unemployment coverage* is measured annually, we use it along with *EPL* to assess the time-series relationship between labor protection policies and cross-border acquisitions. A disadvantage of *Unemployment coverage* is that it only measures the proportion of unemployed workers who receive benefits; it does not measure other factors that alter the costs to firms of changing labor contracts.

Panel B of Table 1 presents summary statistics of country and country-pair characteristics. *Unemployment coverage* is 0.38, indicating that across all country-year observations unemployment insurance recipients represent 38% of the unemployed. The average level of *Employment law* and *EPL* is 0.48 and 2.19, respectively. Appendix 2 provides the values of *Employment law*, *EPL*, and *Unemployment coverage* across countries.

¹ The OECD employment protection data can be downloaded on the website: <http://www.oecd.org/employment/protection>.

2.2 Cross-Border acquisitions and firm performance

The Securities Data Company (SDC) database provides data on cross-border acquisitions. Cross-border acquisitions include deals both announced and completed from 1991 through 2012, in which the acquirer and target firm can be publicly listed, privately owned or a subsidiary. Following Erel, Liao, and Weisbach (2012), we exclude leveraged buyouts, spinoffs, recapitalizations, repurchases, self-tenders, exchange offers, privatizations, and transactions that do not disclose the value of the deal.

After merging the SDC with the other data sources discussed below, we have a maximum of 11,485 cross border deals in our regression analyses. There are 3,008 acquirers that make only one cross-border acquisition during our sample period. There are 1,658 acquirers that make 2-4 cross-border deals and 509 acquirers that make five or more cross-border acquisitions.

2.2.1 Acquirer CARs

We use deal-level data to assess the cumulative abnormal returns (CARs) and abnormal returns on assets (ROAs) of acquiring firms following cross-border acquisitions. Based on Masulis, et al. (2007) and Ishii and Xuan (2014), we further restrict our definition of a cross-border acquisition. First, the cross-border deal must involve a publicly listed acquirer. Second, we only examine cases in which the acquirer obtains full control (100% ownership of the target) and was not a majority stakeholder before the acquisition. Third, we eliminate small deals (less than \$1 million), since these might differ materially from the bulk of the sample. Fourth, we focus only on nonfinancial firms since financial firms are subject to a wide array of regulatory restrictions on cross-border acquisitions.²

To calculate acquirer CARs around the acquisition announcement dates, we start with

² The results are quite robust to alterations in these criteria. First, the deal-level results are robust to including financial industry firms. Second, the deal-level results hold when defining an acquisition as obtaining a majority stake, rather than defining an acquisition as when the acquiring firms holds 100% of the target's shares after the transaction.

stock price data from Datastream for non-U.S. firms and from CRSP for U.S. companies. We use international exchange rates from Datastream to compute all returns in U.S. dollars. Thus, the dollar-denominated daily return for firm i in country j on day t is

$$R_{i,j,t} = \frac{\left[P_{i,j,t} X\left(\frac{\$}{j}\right)_t \right]}{\left[P_{i,j,t-1} X\left(\frac{\$}{j}\right)_{t-1} \right]} - 1, \quad (1)$$

where $P_{i,j,t}$ is the local currency stock price of firm i , in country j , on day t , and $X(\$/j)_t$ is the spot exchange rate (dollars per local currency) on day t .

We then estimate CARs using the two-factor international market model, as in Bris and Cabolis (2008). The two factors are the local market return and the world market return, where these returns are computed in U.S. dollars. We use the broadest equity market index available for each country to proxy for the local market return and the MSCI world index to proxy for the world market return. Thus, we run the following regression:

$$R_{ijt} = \alpha_i + \beta_i^m R_{mjt} + \beta_i^w R_{wt} + \varepsilon_{it}, \quad (2)$$

where R_{ijt} is the dollar-denominated daily stock return for firm i in country j , R_{mjt} is the local market return in country j , and R_{wt} is the world market return. We estimate the model using 200 trading days from event day -210 to event day -11 and compute five-day CARs from the ε 's during the event window $(-2, +2)$, where event day 0 is the acquisition announcement date. Thus, there is one CAR for each deal.

2.2.2 Acquire abnormal ROA

To measure the change in a firm's performance when it acquires another firm, we construct a measure of abnormal operating performance based each firm's ROAs, which equals net income divided by the book value of total assets at the beginning of the fiscal year. We then

calculate abnormal operating performance (industry-median-adjusted ROAs) before and after a cross-border acquisition. The two-digit SIC industry codes are based on the self-reported main industry classification of the firm. In pre-merger years, industry-median-adjusted ROAs equal the weighted average of the acquirer and target's ROAs minus the weighted average of their respective industry-median ROAs. The weights are based on the market values of each firm in the year before the acquisition (year -1). The industry classification is based on two-digit SIC codes. In post-merger years (years +1, +2 and +3), industry-median-adjusted ROAs are the merged firm's ROAs minus the weighted average of the acquirer's and targets industry-median ROAs.

Specifically, pre-acquisition industry-median-adjusted ROA equals

$$(ROA_a * w_a + ROA_t * w_t) - (ROA_{a_{ind}} * w_a + ROA_{t_{ind}} * w_t), \quad (3)$$

while post-acquisition industry-median-adjusted ROA equals

$$ROA_{firm} - (ROA_{a_{ind}} * w_a + ROA_{t_{ind}} * w_t). \quad (4)$$

The terms are defined as follows: ROA_a is the acquirer's ROAs; ROA_t is the target's ROAs; $ROA_{a_{ind}}$ is the acquirer's industry-median ROAs; $ROA_{t_{ind}}$ is the target's industry-median ROAs; ROA_{firm} is the merged firm's ROAs; w_a is the weight of the acquirer firm; and w_t is the weight of the target firm. The weights are the respective market value of the firm relative to the market value of the combined firms in the year before the acquisition (year -1). Since (a) we only have ROA for publicly-traded acquirers and targets and (b) the analyses of abnormal ROAs require three years of data following the acquisition, the sample size drops appreciably from that in the CAR analyses.

2.2.3 Deal-level and firm-level characteristics

The deal-level analyses control for firm-level and deal-level characteristics that past researchers have used to explain firm performance and CARs (e.g., Masulis, et al. 2007). First, we control for acquiring firm traits, such as firm size, cash flow, Tobin's Q, and leverage, which are obtained from Worldscope and Compustat. Second, we control for the acquiring firm's pre-announcement stock price run-up, which is measured as the acquirer's market-adjusted buy-and-hold return during the 200-day window from 210 days before the acquisition through 11 days before the acquisition [-210, -11]. Third, we control for deal-level traits provided by SDC: relative deal size equals the ratio of transaction value to the acquirer's book value of total assets in the fiscal year prior to the announcement date; industry relatedness equals one if the acquirer and the target share a two-digit SIC industry classification; public target dummy, private target dummy, and subsidiary target dummy equal one if the target is respectively a publicly-traded parent company, privately-owned parent company, or a subsidiary firm; and, similarly, all cash deal, friendly deal, and tender deal equal one respectively if the purchase is an all-cash deal, if the target company's board recommends the offer, and if the takeover bid is a public offer to acquire a public firm's shares made to equity holders during a specified time.

Panel A of Table 1 presents summary statistics for the 11,485 cross-border deals. The five-day CAR is 1.31% across all cross-border acquisitions, suggesting that on average cross-border acquisitions enhance acquirer value. The average transaction value is 31.8% of the acquiring firm's total assets. The acquirer and target have different two-digit SIC industry codes in 43% of the deals, which is reflected in the dummy variable *Unrelated deal*, and which is about the same ratio as in domestic acquisitions. Publicly traded target firms account for about 10% of deals; thus, 90% of targets are privately held firms or subsidiaries of firms. We "winsorize" continuous variables at the 1st and 99th percentiles. Furthermore, when we restrict the sample to firms that do not conduct cross-border and domestic acquisitions within ten days of each other, the results hold, yielding results that are similar both in terms of statistical significance and economic magnitudes. Appendix 1 provides variable definitions. And Appendix 3 provides

information on the total number of cross-border deals for each acquirer country and target country in our sample.

2.3 Cross-border acquisition activity and country and country-pair control variables

In extensions of our deal-level analyses of CARs and abnormal ROAs, we examine three indicators of cross-border acquisition activity. Cross-border dollar volume measures the dollar value of transactions and equals $\text{Log}(1 + \text{Value}(a,t))$, where $\text{Value}(a,t)$ is the total dollar value of all cross-border mergers during the sample period for acquirer firm a , with a target from country t . Cross-border number measures the number of transactions and equals $\text{Log}(1 + \text{Number}(a,t))$, where $\text{Number}(a,t)$ is the total number of all cross-border mergers during the sample period for acquirer firm a , with a target from country t . Cross-border deal size measures the average size of transactions and equals $\text{Log}(1 + \text{Deal size}(a,t))$, where $\text{Deal size}(a,t)$ is the average dollar value of all cross-border deals during the sample period for acquirer firm a , with a target from country t .

Figures 1 – 4 provide illustrative patterns. Cross-border acquisitions are large, growing, and represent an increasing proportion of the value of all mergers and acquisitions. As shown in Figure 2, during the early part of the sample (1991-1997), cross-border acquisitions were typically less than \$300 billion per annum, but this rose to about \$800 billion per annum after the early 2000s. Furthermore, Figure 1 shows that the value of cross-border deals rose from about 25% of all acquisitions during the early part of the sample (1991-1997) to around 35% since then. Figure 3 documents the value of acquisitions for the eleven largest countries in terms of the total value of cross-border acquisitions over the period from 1991 through 2012. The U.S. and U.K. are the largest acquirers, with total values of over \$2 trillion. Figure 4 shows that a larger volume of acquisitions involves targets in countries with weaker labor regulations than targets in countries with stronger labor regulations than the acquirer country.

We also include data on country characteristics that have been used to explore the determinants of cross-border acquisitions. First, considerable research indicates geographic and

cultural proximity facilitates communication, deal-making, and hence cross-border acquisitions, as shown in Erel et al. 2012. Consequently, we include three variables to capture these traits: (a) the natural logarithm of the distance between the capitals of the acquirer and target countries, *Log[Geographic distance]*; (b) an indicator variable that equals one if the acquirer and the target have the same primary language (*Same language*); and (c) an indicator variable that equals one if they have the same primary religion (*Same religion*). Second, we include *Log[GDP per capita]* and *Log[Population]* to measure the level of economic development and size of the population respectively. Third, since other country traits might influence the costs and benefits of cross-border transactions, we include acquirer and target country fixed effects, and in some analyses, we include acquirer-target fixed effects for all country pairs. In Panel B of Table 1, we observe that 4% of country-pairs share the same language and about 20% of country-pairs share the same religion.

2.4 Preliminaries: Do cross-border acquisitions predict changes in labor regulations?

In this research, we seek to assess (1) whether the stock market response to a firm making a cross-border acquisition differs depending on the comparative strength of labor regulations between the acquiring and target countries, and (2) whether the change in the operating performance of the acquiring firm depends on the differences in labor regulations in the acquiring and target countries. If acquisition activity triggers changes in labor regulations, however, this would complicate our ability to draw confident inferences about the impact of comparative labor regulations on cross-border deals.

Thus, we assess the degree to which acquisition activity forecasts changes in labor regulations. We regress changes in *Unemployment coverage* ($\Delta Unemployment\ coverage$) and changes in *EPL* (ΔEPL) between period $t-1$ and t on the average value of cross-border acquisitions between period $t-4$ and $t-1$ (*Cross-border dollar volume_3y*). We also control for lagged values of *Unemployment coverage* (*EPL*), measures of economic and institutional development, as well as year fixed effects. Data permitting, the regressions include 50 countries

over the period from 1993 to 2012.

As shown in Table 2, there is no evidence that cross-border acquisition activity accounts for changes in labor regulations. Indeed, the t-statistics on cross-border volume during the previous three years are less than one in the regressions. The weakness of this relationship holds when altering the conditioning information set. For example, the t-statistics remain less than one when omitting the lagged labor regulation regressors or when omitting GDP growth. While these results do not establish that labor regulations are exogenous, they do indicate that the value of cross-border acquisitions is not strongly related to future changes in labor laws.

3. Empirical results

This section examines the relationship between labor regulations and (1) acquirer CARs around the announcement of an acquisition and (2) acquirer abnormal ROAs following cross-border acquisitions. In these analyses, we also test whether comparative labor regulations exert a particularly pronounced effect on acquirer CARs and abnormal ROAs when the target firm is in an industry in which labor flexibility is relatively important. If labor flexibility is especially important for the success of some firms and stronger labor protection laws impede labor flexibility, then an acquirer's CARs and abnormal ROAs should be more sensitive to the target country's labor protection laws when the target is in an industry that relies heavily on labor flexibility. In turn, if labor flexibility is relatively unimportant for a target firm's success, then labor regulations should be comparatively less important in shaping the acquirer's CARs and abnormal ROAs. We begin with baseline regressions that do not distinguish targets by industry and then differentiate firms by their dependence on labor flexibility.

3.1. Labor regulations and CARs: Baseline Assessments

In Table 3, we use the following specification:

$$CAR_d = \beta_0 + \beta_1 Labor\ Regulation[t-a]_d + \beta_2 D_d + \beta_3 A_d + \beta_4 C_d +$$

$$+ \delta_a + \delta_t + \delta_y (+ \delta_{at}) + u_d \quad (5)$$

where CAR_d is, for deal d , the acquirer's five-day CAR (-2, +2) surrounding the cross-border acquisition announcement, $Labor\ Regulation[t-a]_d$ is the difference between in labor regulations (*Unemployment coverage*, *Employment law*, or *EPL*) between the target and acquiring firm countries, D_d , A_d , and C_d are deal, acquiring firm, and country characteristics for countries of the acquiring and target firms respectively, δ_a , δ_t , δ_y , and δ_{at} are fixed effects for the country of the acquiring firm (a), the country of the target firm (t), the year (y), and acquirer-target country fixed effects (at), and u_d is the error term for deal d . To isolate the relationship between CAR and labor regulation differences, we control for deal (D_d), acquirer (A_d), and country traits (C_d) that past researchers have shown help explain acquisition announcement returns (e.g. Fuller, Netter and Stegemoller, 2002; Masulis, Wang, and Xie, 2007). These controls were discussed in Section 2 and are more completely defined in Appendix 1. We can control for acquirer-target country fixed effects (δ_{at}), and therefore control for all country-pair traits, when (a) firms from the acquiring country acquire firms from the target country in different years and (b) *Labor Regulation[t-a]* varies over time.

The results in Table 3 indicate that cumulative abnormal returns are materially smaller when an acquiring firm announces the purchase of a target firm in a country with more generous labor policies, as measured by *Unemployment coverage*, than the acquirer's home country. That is, the market tends to respond more favorably when a firm acquires a target in an economy in which unemployment benefits cover a smaller proportion of uninsured workers. More specifically, column (1) includes all of the control variables except country-level fixed effects; column (4) also includes acquirer and target country effects; and column (7) includes acquirer-target fixed. *Unemployment coverage* enters all regressions negatively and significantly at the five percent level. In terms of economic size, the estimate in column (7) suggests that when an acquirer purchases a target in an economy with a one standard deviation larger value of *Unemployment coverage* (0.42) than the value of its home country, its CAR will be about 0.34

($=0.42*(-0.804)$) smaller than if the target is in a country with the same *Unemployment coverage*. Figures 5a and 5b illustrate these findings: CARs tend to be larger when the target is in a country with weaker labor regulations than the labor regulations in the acquiring firm's home country.

The control variables enter the CARs regressions in a manner that is consistent with previous studies of cross-border acquisitions. For example, we find that large acquirers have lower abnormal returns and acquisitions involving large targets (relative deal size) have higher abnormal returns. We also confirm that announcement returns are significantly lower for acquirers that experience a rapid pre-announcement rise in stock prices (Stock runup). In addition, we find that acquisitions of private or subsidiary targets are associated with higher announcement returns, while acquisitions of public targets are associated with lower announcement returns.

The baseline results on *Employment law* and *EPL* are not as strong. In particular, while *Employment law* enters the CARs regression significantly at the one percent level when we do not include country fixed effects (column 2), the estimate becomes insignificant when including dummy variables for the acquiring and target countries in column (4). With respect to *EPL*, Table 3 indicates that coefficient estimate on *EPL* is negative and statistically significant at the 1% level when we include all of the control variables except country fixed effects. However, the estimate becomes insignificant when we include country-level fixed effects. Since the *EPL* measure captures some country-level changes in dismissal protection, we include the country-pair fixed effects in column (8) and find that *EPL* enters the CAR regression significantly at the ten percent level.

One possible explanation for the weaker results on *Employment law* and *EPL* is that labor protection laws primarily influence the CARs of the acquirer when the target's profitability relies heavily on the flexibility of labor markets. Perhaps, by failing to distinguish target firms by the degree to which they benefit from the flexibility of labor markets, we have not identified the key mechanism linking the stock market's response to cross-border acquisitions and labor regulations.

3.2. Labor regulations and CARs: The target's labor intensity and volatility

We now reassess the relationship between acquirer firm CARs and labor regulations while differentiating by the degree to which the target firm is in an industry whose performance is likely to depend heavily on labor regulations. To measure the degree to which an industry (3-digit SIC code) is likely to depend heavily on labor regulations, we construct and use two benchmark indicators of labor dependence based on U.S. data: (1) *Labor intensity* equals one if the target industry's average ratio of labor and pension expenses to sales is greater than the sample median and zero otherwise; and (2) *Labor volatility* equals one if the target industry's average ratio of the standard deviation of the number of employees relative to the value of PPE assets (plant, property, and equipment) is greater than the sample median and zero otherwise. That is, using the U.S. economy to benchmark industries, we construct these two proxies of the degree to which the performance of firms in a particular industry depends heavily on labor market flexibility. If the difference in labor regulations between acquirer and target countries materially influences the stock market's reaction to a cross-border acquisitions, then we should discover that acquirer CARs are particularly responsive when the target is in a labor intensive industry or an industry that has comparatively volatile demand for labor.

More specifically, we modify equation (5) to allow for the relationship between CARs and labor regulation differences to vary with the degree to which the target is in a labor dependent industry:

$$CAR_d = \beta_0 + \beta_1 Labor\ Regulation[t-a]_d + \beta_2 Labor\ Regulation[t-a]_d * Labor\ Dependence[t]_d + \beta_3 D_d + \beta_4 A_d + \beta_5 C_d + \delta_a + \delta_t + \delta_y (+ \delta_{at}) + u_d \quad (6)$$

where *Labor Dependence[t]_d* is one of the proxies—*Labor intensive* or *high labor volatility*—

of the degree to which the industry of the target firm depends on labor market flexibility for its success and the other variables are the same as those used in equation (5). In Table 4, Panel A presents the results when interacting *Labor intensive* with *Unemployment coverage*, *Employment law* and *EPL* respectively, while Panel B presents the results when interacting *High labor volatility* with *Unemployment coverage*, *Employment law* and *EPL* respectively.

We find that the sensitivity of acquirer announcement returns to differences in labor regulations is much larger for targets in labor dependent industries. Consider first the *Unemployment coverage* results, which Table 4 provides in columns (1) and (4) in both Panel A and B. The difference between *Unemployment coverage* in the target and acquirer country enters negatively and significantly in both the *Labor intensive* and *high labor volatility* regressions. Moreover, the coefficients on the interaction terms enter negatively and significantly, at the 10% level for the interaction between *Unemployment coverage* and *Labor intensive* (column 1, panel A) and at the 1% level for the interaction between *Unemployment coverage* and *High labor volatility* (Column 1, Panel B). After controlling for the country pair fixed effects, we continue to find a 1% significance level for the interaction between Unemployment coverage and High labor volatility (Column 4, Panel B).

The economic impact is large: the estimated increase in an acquirer's CARs for purchasing a target in an economy with lower *Unemployment coverage* than its home country is twice as large when the target is in a comparatively high volatility industry than when the target is in a low volatility industry in the same target country. For example, consider a Swedish firm (Sweden has an average value of Unemployment coverage of 0.796) acquiring a target firm in the United States (which has an average value of Unemployment coverage of 0.362). The estimates from Table 4 indicate that if the target is in the computer programming service industry (SIC 737), which is a comparatively high labor-volatility industry, the additional increase in the acquiring firm's CAR (above the average increase) will be 0.61% ($=(0.796-0.362) * (0.660+0.757)$). However, if the target is in the dairy products industry (SIC 202), which is a low labor-volatility industry, the corresponding additional boost in CAR (above the average increase

associated with an acquisition) will be 0.29% ($= (0.796 - 0.362) * 0.660$). Given that the average CAR is 1.3%, the difference is economically significant.

In assessing the relationship between the CAR of cross-border acquisitions and labor regulations, we find that it is especially important to differentiate targets in high and low labor dependent industries when considering the *Employment law* and *EPL* proxies of labor regulations. As shown in Table 4, the interaction terms between *Employment law* and both *labor intensive* and *high labor volatility* enter negatively and significantly. The stock market responds positively when an acquiring firm purchases a target in an economy with weaker labor protection laws when the target firm is in an industry in which labor protection laws are likely to exert a pronounced effect on its performance. For *EPL*, the interaction terms between *EPL* and both *labor intensive* and *high labor volatility* enter negatively and significantly (at the 1% level and 5% level, respectively). After controlling for country pair fixed effects, we continue to find significant interaction terms between *EPL* and both labor intensive and high labor volatility (column 5, Panel A and B). Overall, these results indicate that the sensitivities of CARs to differences in labor regulations are larger for targets in labor dependent industries.

That is, the CARs of acquiring firms respond most strongly to cross-border acquisitions when the target is in an industry and a country in which theories focusing on the importance of labor regulations predict markets will be most sensitive. The economic impact is large. For example, consider a firm in Germany (which has a value of *Employment law* of 0.702) acquiring a target in Malaysia (which has a value of *Employment law* of 0.189). The estimates suggest that acquirer CARs will rise by 0.44% ($= (0.702 - 0.189) * 0.864$) more if the target firm is in a high-volatility industry than if the same acquirer purchases a target in Malaysia but in a low-volatility industry.

3.3. Labor market regulations and ROA: Simple comparisons

Having shown that stock prices respond more favorably to the cross-border acquisition of firms in target countries with weak labor protection laws, especially if those firms are in labor intensive industries or industries with high labor volatility, we now examine firm performance.

We examine whether the abnormal ROAs of an acquiring firm varies negatively with the comparative strength of labor regulations in the target and acquiring countries. Furthermore, we assess whether the relationship between acquiring firm abnormal ROAs and the target-acquirer difference in the strength of labor regulations varies by the industry of the target firm.

We use two methods to evaluate whether acquiring firm performance following a cross-border acquisition depends on the comparative strength of labor regulations in the target and acquiring country. The first method simply examines changes in the abnormal ROAs of the acquiring firm around cross-border acquisitions. In particular, we partition the sample into “ $T < A$ ” and “ $T > A$ ” groups, where “ $T < A$ ” means that the target country has weaker labor regulations than the acquirer’s country, and “ $T > A$ ” means that the target country has stronger labor regulations than the acquirer’s country. We continue to use three measures of labor regulations: *Unemployment coverage*, *Employment law* and *EPL*. We then compute for each of these measures of labor regulations the change in abnormal ROA of the acquiring firm following the acquisition announcement.

As shown in Table 5, abnormal firm performance—the average industry-median-adjusted ROAs—for the “ $T > A$ ” group drops significantly after cross-border acquisitions, but abnormal firm performance does not drop for the “ $T < A$ ” group. The post-acquisition 3-year median abnormal ROAs is significantly below the year -1 abnormal ROA for cross-border deals involving targets from countries with relatively protective labor regulations and unemployment benefits that cover a large proportion of the unemployed. In contrast, there is no significant change in abnormal operating performance for deals in the “ $T < A$ ” group. The tests of significance for the post-acquisition 3-year median abnormal ROAs are conducted using a null hypothesis of zero change in abnormal ROA.³ These results are consistent with the view that stronger labor regulations in the target country make post-merger integration more costly and

³ When we test the differences between the $T > A$ and $T < A$ groups, we find that abnormal operating performance are not significantly different for the *Unemployment coverage* analyses, but are significantly different at the 10% level for the *Employment law* and *EPL* analyses. As shown in Table 6, these differences become more distinct when differentiating by the labor dependence of the target firm.

reduce the manifestation of synergies in the acquirer's ROAs. For instance, if a firm from the U.S. (which has weak labor regulations) acquires a firm in France (which has strong labor regulations), then "T>A" for Employment law. The regression estimates then predict a decrease in abnormal ROA of 0.0255 from the pre-acquisition period to the post-acquisition 3-year median abnormal ROA. The estimate suggests that the post-acquisition abnormal ROA is 26.8% ($=100*0.0255/0.0953$) lower than its pre-acquisition value average.

Table 6 extends these analyses by further differentiating by the industry of the target firm. In addition to examining abnormal firm performance when differentiating between cross-border acquisitions when the target country has stronger labor regulations than the acquiring country ($T > A$) or weaker labor regulations ($T < A$), we now differentiate by whether the target firm is in a labor dependent industry as measured by *labor intensity* or *labor volatility*. As in the analyses of acquirer CARs, this further cutting of the data provides a precise identification of whether cross-country differences in labor regulations influence an acquiring firm's performance in manner that is consistent with the predictions emerging from several theories discussed in the Introduction.

As shown in Table 6, the abnormal ROAs of the acquiring firm perform much worse when the target is in a country with stronger labor protection laws and more expansive unemployment benefits than those in acquiring firm's home country, and these findings are driven by target firms in labor intensive industries or industries with high labor volatility. In particular, Table 6 shows that when either *Unemployment coverage*, *Employment law*, and *EPL* are greater for the target country than the acquirer, abnormal ROAs of the acquirer are significantly smaller when the target is in either a labor intensive industry or an high labor volatility industry than when the target is in the same country but is not in a labor intensive or high labor volatility industry. It is the combination of target country's labor regulations/policies and the degree to which the target firm is in a labor intensive or high labor volatility industry that drives the acquiring firm's response, as measured by abnormal ROAs, to the cross-border deal.

3.4. Labor market regulations and ROA: Regression analyses

The second method for assessing abnormal operating performance employs a regression framework based on Healy, Palepu and Ruback (1992) and controls for deal and firm characteristics. The dependent variable is the abnormal ROAs of the acquiring firm during the three years following the acquisition, so that there is one observation per deal. Following Healy, Palepu and Ruback (1992), the regression controls for the combined acquirer-target abnormal ROAs in the year before the acquisition, i.e., pre-acquisition industry-median-adjusted ROA defined in equation (3) above. The regression also controls for $\text{Log} [\text{Total Assets}]$, which is the natural logarithm of the book value of the assets of the acquiring firm (in millions of U.S. dollars) in the year before the acquisition, *Tobin's Q*, which is the market value of total assets divided by the book value of total assets of the acquiring firm in the year before the acquisition; and two dummy variables defining the nature of the acquisition *Unrelated deal*, which indicates whether the deal involves distinct industries, and *Friendly deal*, which indicates whether the acquisition is friendly.

The estimated coefficient on the intercept represents the conditional average change in abnormal operating performance following cross-border mergers. We provide these regressions separately for targets from countries with higher labor regulation (*Unemployment coverage*, *Employment law*, and *EPL*) values than those in acquirer countries and targets from countries with less protective labor regulations than those in acquirer countries.

The regression results from this second method indicate that acquirers that purchase targets in countries with stronger labor protection regulations than their own country's labor regulations tend to suffer worse performance following the deal. The results in Table 7 indicate that acquirer abnormal ROA falls when the target is in a country with more protective labor laws and more expansive unemployment benefits coverage. As shown, the estimated intercept is negative and statistically significant for all the "T > A" groups and insignificant for all the "T < A" groups. These results imply that acquirers from countries with weaker labor regulations experience significantly worse operating performance following cross-border acquisitions, while

acquirers from countries with stronger labor regulations do not. Firm performance tends to drop following cross-border deals in which the target is in a country with more generous unemployment benefits and stronger employment laws.

In Table 8, we extend these results and further differentiate by deals by whether the target is in a labor dependent industry. The results are again striking. All of the estimated reduction in abnormal ROAs from the acquisition of a firm in a country with strong labor protection policies emerges from the purchase of firms in labor intensive and high labor volatility industries. Put differently, the positive synergies from the cross-border acquisition of a firm in a country with weaker labor protection laws and less expansive unemployment benefits are largely due to the purchase of target firms in industries that rely heavily on flexible labor markets, such as labor intensive industries and industries in which labor fluctuates relatively severely.

3.3. A check: The number, volume, and size of cross-border acquisitions

We now check whether our findings on CARs and ROAs are consistent with a firm's decisions regarding whether and where to engage in cross-border acquisitions. If labor regulations shape the stock price reaction to cross-border acquisitions and profitability of such deals, then this should be reflected the incidence and size of cross-border acquisitions when differentiating country-pairs by labor regulations. To check the consistency of our deal level analyses with firm-level decisions to undertake cross-border mergers and acquisitions, we regress the number, value, and deal size of cross-border acquisitions on the difference between labor regulations in the target and acquirer countries, while controlling for an assortment of firms, country, and country-pair characteristics.

We augment the standard gravity model of cross-border mergers and acquisition activity to assess the relationship between labor market regulations and the number, volume, and size of cross-border acquisitions. Our sample consists of public acquirers that consummate at least five cross-border deals during our sample period. We consider every possible target country into which these acquiring firms might choose to make an acquisition. Thus, the unit of analysis is an

acquiring firm (a) and its (potential) acquisition of firms in each target country (t). If a firm does not acquire a target in a specific country, we assign a zero for number and value in acquisitions to that country.

We estimate the following equation

$$y_{at} = \beta_0 + \beta_1 Labor\ Regulation[t-a]_{at} + \beta_3 D_{at} + \beta_4 A_a + \delta_a + \delta_t + \delta_i + e_{at}, \quad (7)$$

where the dependent variable, y_{at} , is either $Log(1 + Number(a,t))$, $Log(1 + Value(a,t))$, or $Log(1 + Deal(a,t))$; where $Number(a,t)$, $Value(a,t)$, and $Deal(a,t)$ equal total number, total dollar value, and average deal size of cross-border deals between acquiring firm a and firms in a target country (t); $Labor\ Regulation[t-a]_{at}$ is the difference in labor regulations between the countries of the target and acquiring firms (*Unemployment coverage*, *Employment law*, and *EPL*); A_a represents information about the acquiring firms, such as firm size; and δ_a , δ_t , and δ_i are fixed effects for the acquiring country, the target country, and the industry of the acquiring firm respectively. For each acquiring firm, we use the average annual values for the full sample period (1991-2012) for all time-variant variables.

As shown in Table 9, a country's firms acquire more firms and spend more on acquisitions in another country if that target country's labor regulations are relatively less protective of labor. In particular, the first three columns present OLS regressions in which the dependent variable is $Log(1 + Number(a,t))$, the next three present regressions in which the dependent variable is $Log(1 + Value(a,t))$, and the final three present regressions in which the dependent variable is $Log(1 + Deal(a,t))$. Across all nine specifications, the estimated coefficients on labor market regulation differences are negative and statistically significant. These results imply that, the number and volume of cross-border acquisitions are lower when targets are in countries with greater *Unemployment coverage*, *Employment law*, and *EPL* values than the regulations in the acquirer country. Consistent with our findings that stock returns and profits rise more when the acquiring firm's country has more protective labor regulations than

the target's country, we also find that comparative labor regulations are closely linked with cross-border acquisition activity.

The relationship between labor regulation differences and cross-border acquisition flows is economically large. Two examples illustrate the economic magnitudes from estimates in Table 9. First, consider a target country that has a one standard deviation lower value of *Employment law* than the acquirer (0.18). The estimates indicate that *Value (a,t)* will be about 69% ($=0.18*3.82$) larger than when the two economies have the same labor protection laws. Second, consider France, which is at the 90th percentile of the *Employment law* distribution (e.g., France's Employment law index equals 0.744). From the regression estimates in Table 9, we can compute the drop in foreign firm acquisitions of French companies due to its comparatively strong labor protection laws, where the average country has an employment law index of 0.478. The estimates suggest that relative to an average country, France is associated with 102% ($= (0.744-0.478)*3.82$) lower foreign capital inflows from cross-border acquisitions due to its comparatively strong labor regulations. For countries at the 75th percentile of the *Employment law* distribution (e.g., Italy, has an employment law index of 0.65), they are associated with 66% ($= (0.65-0.478)*3.82$) less foreign capital inflows from cross-border acquisitions due to their labor regulations.

We also explore whether differences in labor regulation between acquirer country and target country operate at the intensive margin, the extensive margin, or both. That is, we examine whether differences in labor regulations shape average deal size. As shown in the last three columns of Table 9, labor regulations operate on both margins. The average deal size of cross-border acquisitions tends to be smaller when targets are in countries with stronger labor protection laws than the regulations in the acquirer country. Stronger labor regulations in a country reduce the dollar value, the number, and the average size of acquisitions by foreign firms in that country.

5. Conclusion

Using a comprehensive sample of cross-border acquisitions from 50 countries occurring from 1991 through 2012, we discover that cross-country differences in labor market regulations help account for (1) the stock price response of the acquiring firm to a cross-border deal and (2) the change in the operating performance of the acquiring firm after it makes a cross-border acquisition. Specifically, the abnormal stock returns and profits of acquiring firms increase more when the target country has weaker labor protection laws.

These effects are more pronounced when the target firm is in an industry that relies heavily on flexible labor markets for its performance. In particular, when the target firm is in an industry in which labor costs account for a large fraction of total costs or an industry in which the volatility of employment is relatively high, the results suggest that the impact of comparative labor regulations on both abnormal stock returns and profits is much larger. The results are consistent with the view the broad array of labor laws, regulations, and policies that shape the operation of labor markets materially shape the direction, performance, and synergies of cross-border acquisitions. As a check, we also find that the number, volume, and deal size of cross-border acquisitions are significantly lower when target countries have stronger labor regulations.

Table 2**The validity test: impact of historical cross-border acquisition volume on labor regulation change**

This table reports the validity test of using labor market regulations to explain cross-border acquisition volume. Specifically, we examine the effect of cross-border acquisition volume on the change of labor regulations for target countries during our sample period. The dependent variables are unemployment benefits coverage change (Δ Unemployment coverage) in Columns (1)-(3) and EPL change (Δ EPL) in Columns (4)-(6). Cross-border dollar volume_3y is the past three year annual average dollar volume of cross-border acquisitions that occurred in the target country. Heteroskedasticity-consistent standard errors are reported in brackets. The coefficient on the constant is suppressed for brevity. *, **, and *** represent statistical significance at the 10%, 5%, and 1% level, respectively.

Dependent variable:	Δ Unemployment coverage			Δ EPL		
	(1)	(2)	(3)	(4)	(5)	(6)
Cross-border dollar volume_3y	0.002 [0.001]	-0.000 [0.002]	-0.001 [0.002]	0.002 [0.004]	0.003 [0.005]	0.002 [0.005]

Table 3**The effect of labor protection on acquirer announcement returns**

This table reports the results of OLS regressions of the effect of labor protection on acquirer abnormal announcement returns. The dependent variable is the acquirer's five-day CAR (-2, +2). Unemployment coverage is unemployment benefits coverage, which is calculated as the ratio of the number of UI (unemployment insurance) benefit recipients to the number of unemployed. Unemployment coverage__[t-a] is the difference between the unemployment benefits coverage for the target and acquirer countries. Employment law is employment laws index, which measures the protection of the individual employment contract (Botero et al., 2004). Employment law__[t-a] is the difference between the employment laws index for the target and acquirer countries. EPL is employment protection laws index, which measures the strictness of employment protection against individual dismissal (compiled by the OECD). EPL__[t-a] is the difference between the OECD employment protection index for the target and acquirer countries. All variables are defined in the Appendix. Heteroskedasticity-consistent standard errors clustered at the acquirer country level are reported in brackets. The coefficient on the constant is suppressed for brevity. *, **, and *** represent statistical significance at the 10%, 5%, and 1% level, respectively.

Table 4**The effect of labor protection on acquirer announcement returns: labor intensity and labor volatility**

This table reports the results of OLS regressions of the effect of labor protection on acquirer abnormal announcement returns. The dependent variable is the acquirer's five-day CAR (-2, +2). Unemployment coverage is unemployment benefits coverage, which is calculated as the ratio of the number of UI (unemployment insurance) benefit recipients to the number of unemployed. Unemployment coverage__[t-a] is the difference between the unemployment benefits coverage for the target and acquirer countries. Employment law is employment laws index, which measures the protection of the individual employment contract (Botero et al., 2004). Employment law__[t-a] is the difference between the employment laws index for the target and acquirer countries. EPL is employment protection laws index, which measures the strictness of employment protection against individual dismissal (compiled by the OECD). EPL__[t-a] is the difference between the OECD employment protection index for the target and acquirer countries. Labor intensive is an indicator variable that equals one if target industry's average labor intensity is above sample median. We calculate labor intensity as the ratio of labor and pension expenses to sales. Labor volatility is defined as the standard deviation of the number of employees scaled by PPE (plant, property, and equipment). High labor volatility is an indicator variable that equals one if target industry's average labor volatility is above sample median. All variables are defined in the Appendix. Heteroskedasticity-consistent standard errors clustered at the acquirer country level are reported in brackets. The coefficient on the constant is suppressed for brevity. *, **, and *** represent statistical significance at the 10%, 5%, and 1% level, respectively.

Table 5**Pre- and post-acquisition abnormal operating performance**

This table reports average industry-median-adjusted operating performance around cross-border mergers for deals that the acquirer country labor protection is stronger than the target country and deals that the acquirer country labor protection is weaker than the target country (Panel A presents summary statistics and Panel B presents industry-adjusted ROA for “T < A” and “T > A”). Year 0 is the year in which the acquisition is completed. ROA is net income divided by the book value of total assets at the beginning of the fiscal year. In pre-merger years, industry-median-adjusted ROA is calculated as the weighted average of the acquirer’s and target’s operating performance minus the weighted average of the industry-median operating performance using the acquirer’s and target’s industry. The weights are based on the market value of total assets of each firm at the year -1. In post-merger years, industry-median-adjusted ROA is the merged firm’s operating performance minus the weighted average of the acquirer’s and target’s industry-median operating performance. Industry classification is based on two-digit SIC codes. Unemployment coverage is unemployment benefits coverage, which is calculated as the ratio of the number of UI (unemployment insurance) benefit recipients to the number of unemployed. Employment law is employment laws index, which measures the protection of the individual employment contract (Botero et al., 2004). EPL is employment protection laws index, which measures the strictness of employment protection against individual dismissal (compiled by the OECD). *, **, and *** represent statistical significance at the 10%, 5%, and 1% level, respectively.

Panel A:

Table 6**Pre- and post-acquisition abnormal operating performance: labor intensity and labor volatility**

This table reports average industry-median-adjusted operating performance around cross-border mergers for deals that the acquirer country labor protection is weaker than the target country. Year 0 is the year in which the acquisition is completed. ROA is net income divided by the book value of total assets at the beginning of the fiscal year. In pre-merger years, industry-median-adjusted ROA is calculated as the weighted average of the acquirer's and target's operating performance minus the weighted average of the industry-median operating performance using the acquirer's and target's industry. The weights are based on the market value of total assets of each firm at the year -1. In post-merger years, industry-median-adjusted ROA is the merged firm's operating performance minus the weighted average of the acquirer's and target's industry-median operating performance. Industry classification is based on two-digit SIC codes. Unemployment coverage is unemployment benefits coverage, which is calculated as the ratio of the number of UI (unemployment insurance) benefit recipients to the number of unemployed. Employment law is employment laws index, which measures the protection of the individual employment contract (Botero et al., 2004). EPL is employment protection laws index, which measures the strictness of employment protection against individual dismissal (compiled by the OECD). Labor intensity is defined as the ratio of labor and pension expenses to sales. Labor volatility is defined as the standard deviation of the number of employees scaled by PPE (plant, property, and equipment). In Panel A, the subsamples are formed based on whether target industry's average labor intensity is above or below sample median. In Panel B, the subsamples are formed based on whether target industry's average labor volatility is above or below sample median. *, **, and *** represent statistical significance at the 10%, 5%, and 1% level, respectively.

Table 7**The effect of labor protection on acquisition synergies**

This table reports the results of Healy, Palepu and Ruback's (1992) regressions for measuring changes in operating performance around cross-border mergers for acquirers with stronger labor protection compared to targets and acquirers with weaker labor protection compared to targets, where post-merger 3-year median abnormal operating performance (ROA) is regressed on the combined acquirer-target industry-median-adjusted operating performance (ROA) in year -1. The intercept represents the average change in abnormal operating performance following cross-border mergers, controlling for pre-merger operating performance. Industry classification is based on two-digit SIC codes. Unemployment coverage is unemployment benefits coverage, which is calculated as the ratio of the number of UI (unemployment insurance) benefit recipients to the number of unemployed. Employment law is employment laws index, which measures the protection of the individual employment contract (Botero et al., 2004). EPL is employment protection laws index, which measures the strictness of employment protection against individual dismissal (compiled by the OECD). Heteroskedasticity-consistent standard errors clustered at the acquirer country level are reported in brackets. *, **, and *** represent statistical significance at the 10%, 5%, and 1% level, respectively.

Table 8**The effect of labor protection on acquisition synergies: labor intensity and labor volatility**

This table reports the results of Healy, Palepu and Ruback's (1992) regressions for measuring changes in operating performance around cross-border mergers for acquirers with weaker labor protection compared to targets, where post-merger 3-year median abnormal operating performance (ROA) is regressed on the combined acquirer-target industry-median-adjusted operating performance (ROA) in year -1. The intercept represents the average change in abnormal operating performance following cross-border mergers, controlling for pre-merger operating performance. Industry classification is based on two-digit SIC codes. Unemployment coverage is unemployment benefits coverage, which is calculated as the ratio of the number of UI (unemployment insurance) benefit recipients to the number of unemployed. Employment law is employment laws index, which measures the protection of the individual employment contract (Botero et al., 2004). EPL is employment protection laws index, which measures the strictness of employment protection against individual dismissal (compiled by the OECD). Labor intensity is defined as the ratio of labor and pension expenses to sales. Labor volatility is defined as the standard deviation of the number of employees scaled by PPE (plant, property, and equipment). In Panel A, the subsamples are formed based on whether target industry's average labor intensity is above or below sample median. In Panel B, the subsamples are formed based on whether target industry's average labor volatility is above or below sample median. Heteroskedasticity-consistent standard errors clustered at the acquirer country level are reported in brackets. *, **, and *** represent statistical significance at the 10%, 5%, and 1% level, respectively.

Table 9

The determinants of cross-border mergers: firm-level analysis

This table reports OLS analysis of the determinants of cross-border mergers and acquisitions. The sample includes public acquirer firms which consummate at least five cross-border deals during our sample period (1991-2012). The dependent variables are $\text{Log}(1 + \text{Number}(a,t))$ in Columns (1)-(3), $\text{Log}(1 + \text{Value}(a,t))$ in Columns (4)-(6) and $\text{Log}(1 + \text{Deal size}(a,t))$ in Columns (7)-(9). $\text{Number}(a,t)$ is the total number of all cross-border mergers during the sample period for acquirer firm a , with the target from country t . $\text{Value}(a,t)$ is the total dollar value of all cross-border mergers during the sample period for acquirer firm a , with the target from country t . $\text{Deal size}(a,t)$ is the average dollar value of all cross-border deals during the sample period for acquirer firm a , with the target from country t . Unemployment coverage is unemployment benefits coverage, which is calculated as the ratio of the number of UI (unemployment insurance) benefit recipients to the number of unemployed. $\text{Unemployment coverage}_{[t-a]}$ is the difference between the unemployment benefits coverage for the target and acquirer countries. Employment law is employment laws index, which measures the protection of the individual employment contract (Botero et al., 2004). $\text{Employment law}_{[t-a]}$ is the difference between the employment laws index for the target and acquirer countries. EPL is employment protection laws index, which measures the strictness of employment protection against individual dismissal (compiled by the OECD). $\text{EPL}_{[t-a]}$ is the difference between the OECD employment protection index for the target and acquirer countries. All variables are defined in the Appendix. Heteroskedasticity-consistent standard errors clustered at the acquirer country level are reported in brackets. The coefficient on the constant is suppressed for brevity. *, **, and *** represent statistical significance at the 10%, 5%, and 1% level, respectively.

Appendix 1: Variable definitions

Variables	Definitions
Cross-border flow	
Log(1+ Number (a,t))	Number (a,t) is the total number of all cross-border mergers during the sample period for acquirer firm a, with the target from country t.
Log(1+ Value (a,t))	Value (a,t) is the total dollar value of all cross-border mergers during the sample period for acquirer firm a, with the target from country t.
Log(1+ Deal size (a,t))	Deal size (a,t) is the average dollar value of all cross-border deals during the sample period for acquirer firm a, with the target from country t.
Labor protection measures	
Unemployment coverage	Unemployment benefits coverage, which is calculated as the ratio of the number of UI (unemployment insurance) benefit recipients to the number of unemployed
Employment law	Employment laws index, which measures the protection of the individual employment contract (Botero et al., 2004). Higher value indicates stronger employee protections.
EPL	Employment protection laws index, which measures the strictness of employment protection against individual dismissal. This index is compiled by the OECD. Higher value indicates stronger employment protections.
Country-level characteristics	
Log [GDP per capita]	The logarithm of annual Gross Domestic Product (in U.S. dollars) divided by the population
Log [Population]	The logarithm of population
Log [Geographic distance]	The logarithm of geographic distance between the capitals of the acquirer and the target countries. We obtain latitudes and longitudes of the capital cities and use the great circle formula to calculate the distance.
Same language	A dummy variable equal to one if the acquirer and the target have the same primary language
Same religion	A dummy variable equal to one if the acquirer and the target have the same primary religion
WGI	The sum of all six Kaufmann et al. (2009) worldwide governance indicators: voice and accountability; political stability and absence of violence/terrorism; government effectiveness; regulatory quality; rule of law, and control of corruption. Each index ranges from -2.5 to 2.5. Higher value indicates better country governance.
Voice and accountability	The extent to which a country's citizens are able to participate in selecting their government, as well as freedom of expression, freedom of association, and a free media (Kaufmann et al., 2009).
Political stability and absence of violence	The likelihood that the government will be destabilized or overthrown by unconstitutional or violent means, including politically-motivated violence and terrorism (Kaufmann et al., 2009).

Rule of law	The extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement, property rights, the police, and the courts, as well as the likelihood of crime and violence (Kaufmann et al., 2009).
Regulatory quality	The ability of the government to formulate and implement sound policies and regulations that permit and promote private sector development (Kaufmann et al., 2009).
Control of corruption	The extent to which public power is exercised for private gain, including both petty and grand forms of corruption, as well as "capture" of the state by elites and private interests (Kaufmann et al., 2009).
Government effectiveness	The quality of public services, the quality of the civil service and the degree of its independence from political pressures, the quality of policy formulation and implementation, and the credibility of the government's commitment to such policies (Kaufmann et al., 2009).
Cumulative abnormal returns	
CAR(-2,+2) (%)	5-day cumulative abnormal returns (CARs) estimated using the market model over the period [-210,-11], where event day 0 is the acquisition announcement date
Firm-level (acquirer) characteristics	
Log [Total Assets]	The natural log of book value of total assets (in millions of U.S. dollars)
Cash flow	Funds from operations divided by total assets
Tobin's Q	Market value of total assets (total assets - book value of common equity + market value of common equity) divided by book value of total assets
Leverage	The ratio of total debt to total assets
Stock runup	Acquirer's buy-and-hold return during the [-210,-11] window minus the market buy-and-hold return over the same period
Deal-level characteristics	
Relative size	The ratio of SDC deal value to the acquirer's book value of total assets at the fiscal year-end prior to the announcement date
Unrelated deal	A dummy variable equal to one for deals in which the acquirer and the target do not have the same two-digit SIC industry
Private target dummy	A dummy variable equal to one if the target is a private firm
Subsidiary target dummy	A dummy variable equal to one if the target is a subsidiary
Public target dummy	A dummy variable equal to one if the target is a publicly traded parent firm

All cash deal	A dummy variable equal to one if the deal is purely financed by cash
Friendly deal	A dummy variable equal to one if the deal is friendly
Tender offer	A dummy variable equal to one if the deal is a tender offer

Appendix 2: Labor regulation variables by country

For labor regulation variables with time-series variation, we report the annual average value during our sample period.

Figure 1: Cross-Border acquisitions as a percentage of total acquisitions

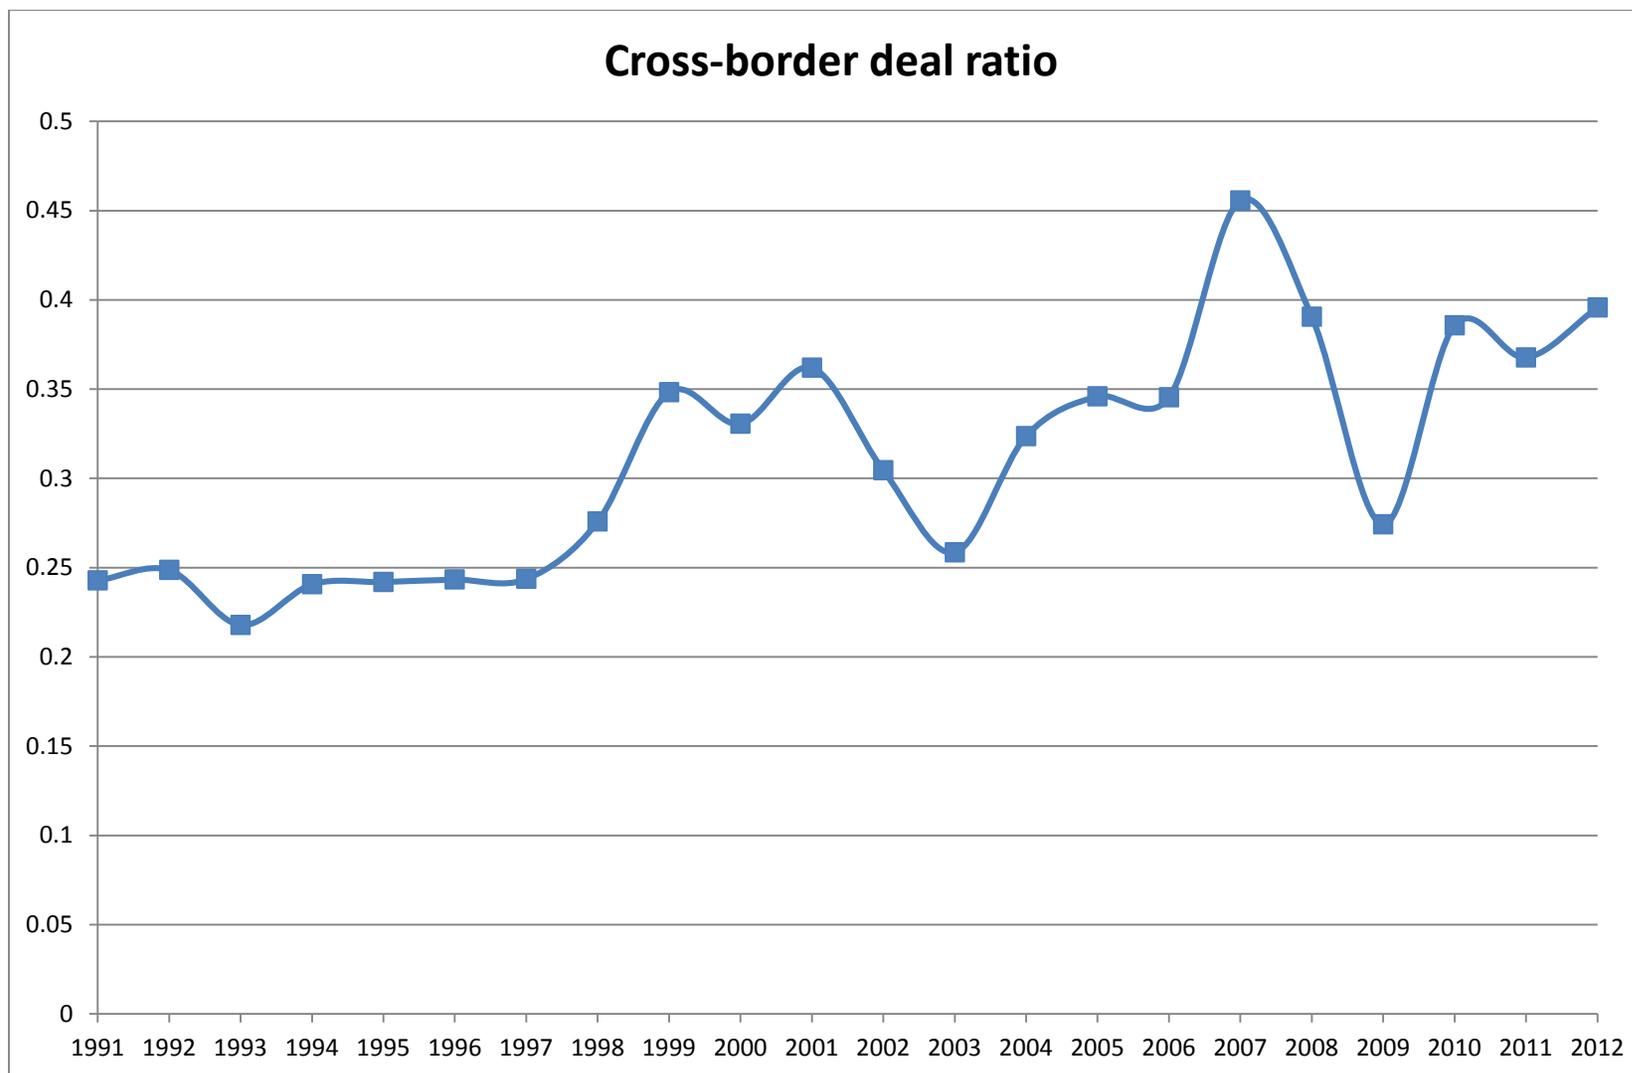

Figure 2: Total value of cross-border and domestic mergers (in Billions of U.S. Dollars) by year

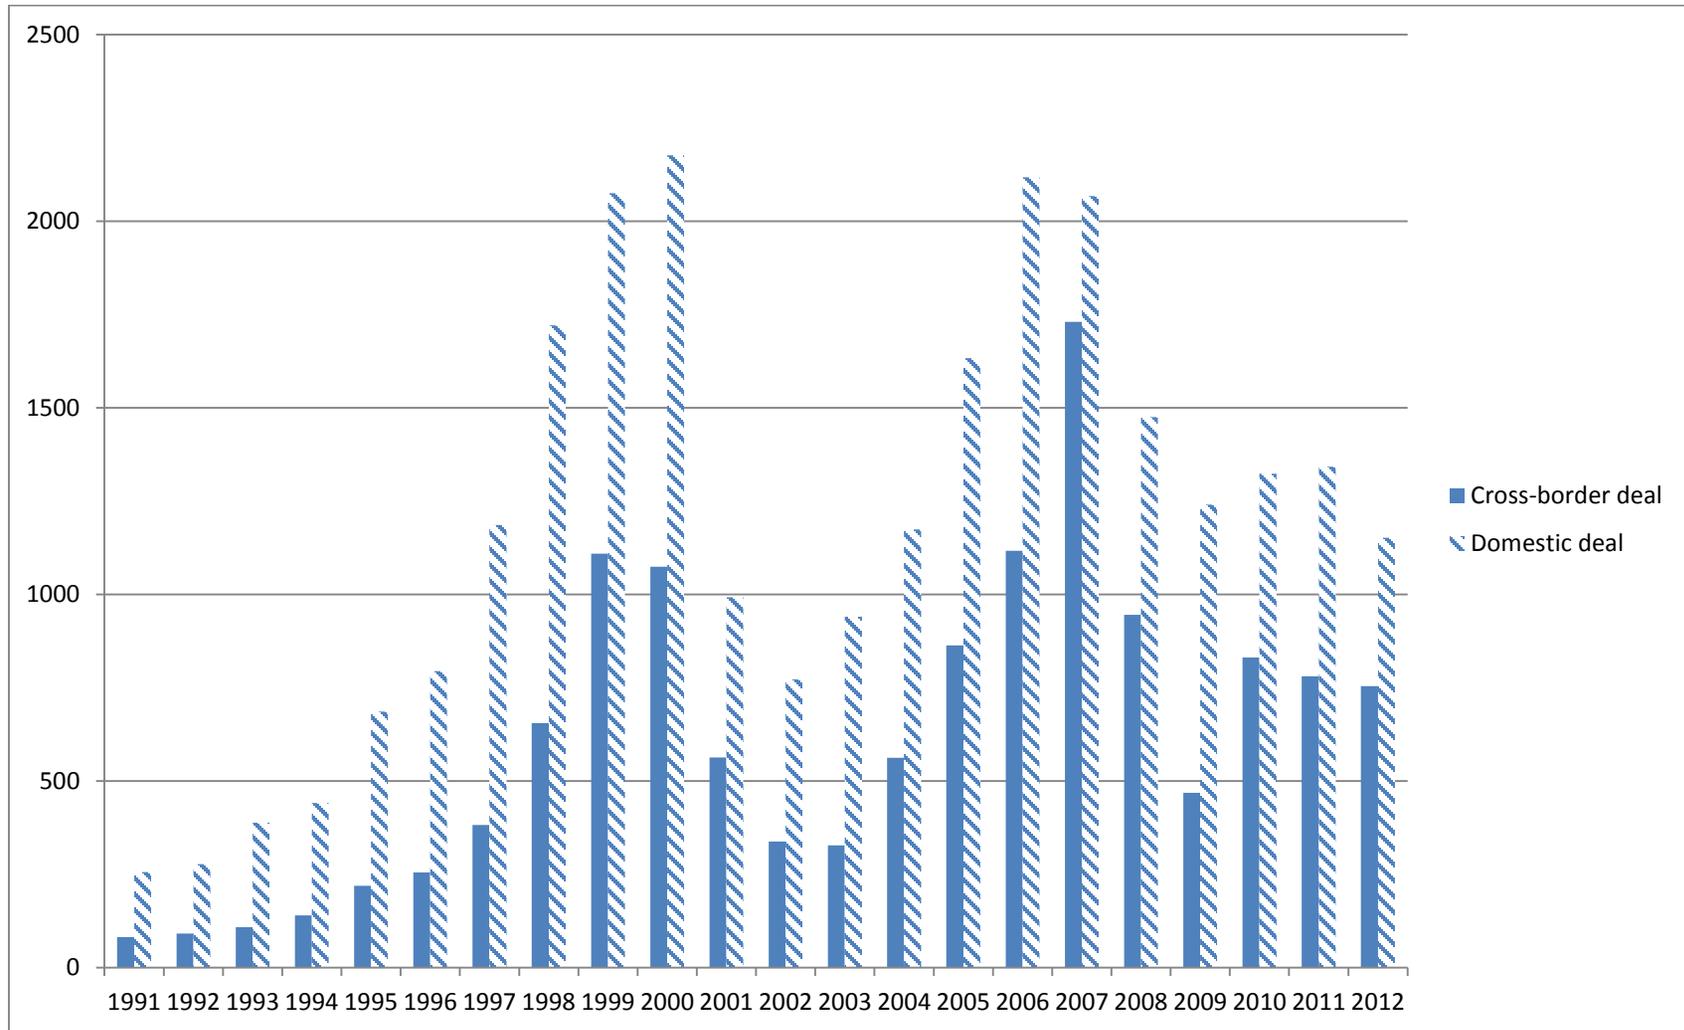

Figure 3: Total value of cross-border mergers by country (in Billions of U.S. Dollars)

This figure depicts information on cross-border acquisitions for the top eleven acquirer countries in terms of cross-border deal value over the entire sample period (1991-2012).

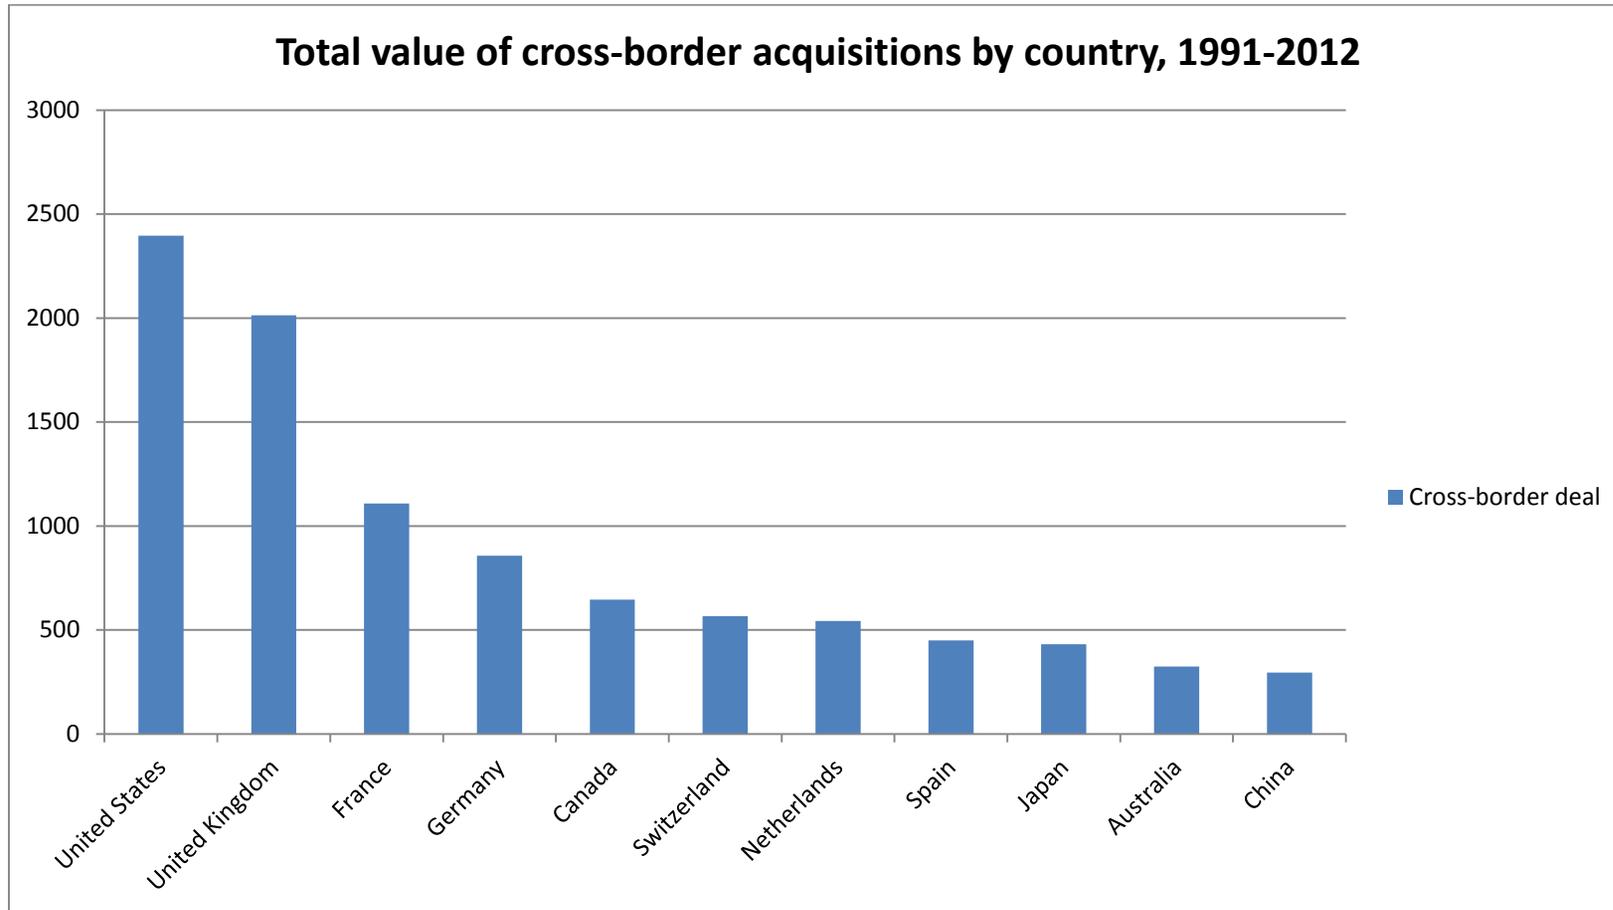

Figure 4: Top acquirer country cross-border acquisition flows

In this figure, weak labor protection laws represent countries with below the 25th percentile of the employment law distribution, and strong labor protection laws represent countries with above the 75th percentile of the employment law distribution. This figure illustrates this information for the top eleven acquirer countries in terms of cross-border deal value over the entire sample period (1991-2012).

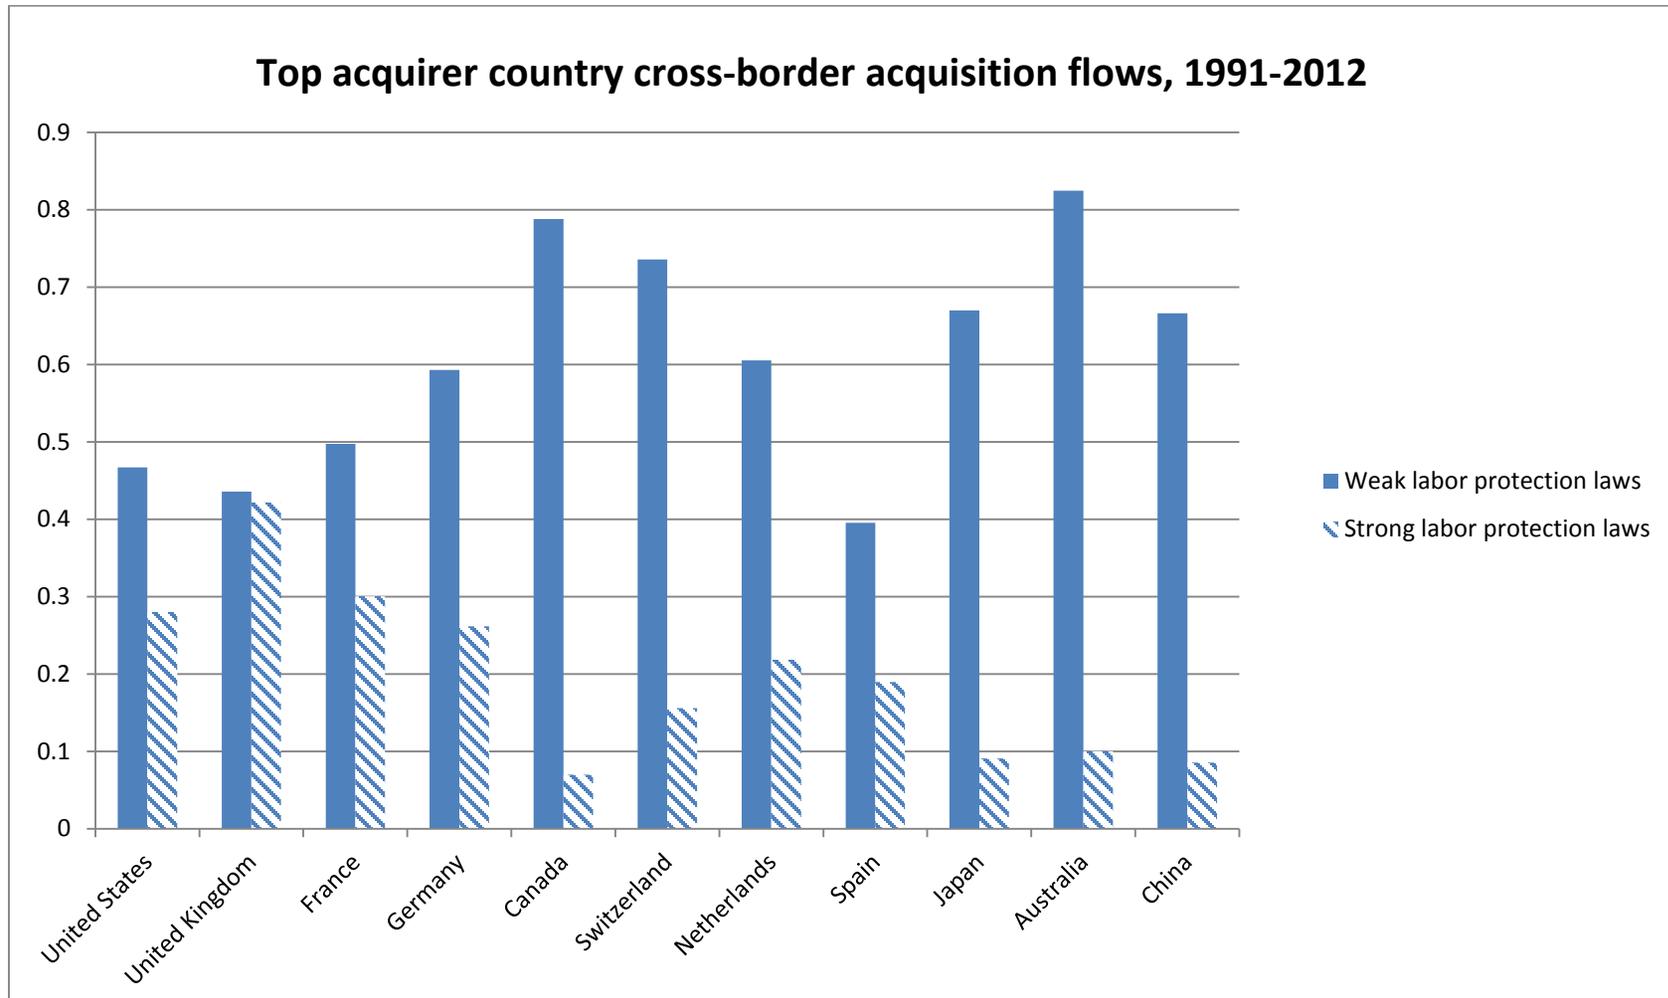

Figure 5a: Acquirer CARs around the acquisition announcement

This figure shows the average acquirer cumulative abnormal returns (%) from day -2 to day +2 around the acquisition announcement (zero is the acquisition announcement date). A>T represents observations with relatively higher employment law for acquirer country, while A<T represents observations with relatively higher employment law for target country.

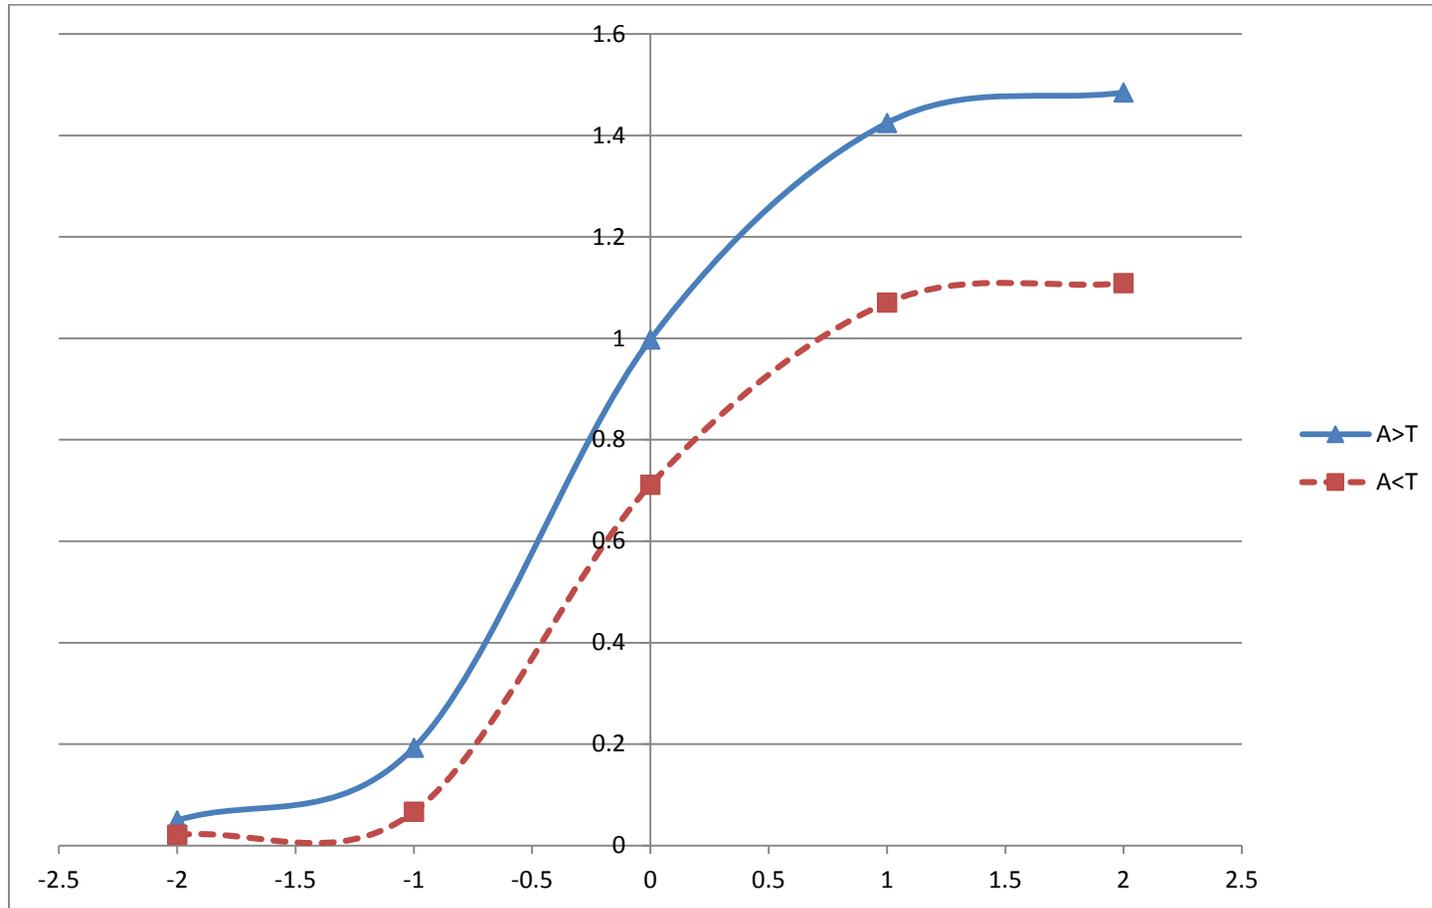

Figure 5b: Acquirer CAR residuals (CAR-R) around the acquisition announcement

This figure shows the average residuals of acquirer cumulative abnormal returns (%) from day -2 to day +2 around the acquisition announcement (zero is the acquisition announcement date). The residuals (CAR-R) are calculated from regression model (2) in Table 4, but exclude the labor regulation variables. A>T represents observations with relatively higher employment law for acquirer country, while A<T represents observations with relatively higher employment law for target country.
